Introduction

Treating allergies often involves giving the person small doses of what they are allergic to. This tends to increase a person’s immunity, or tolerance, to the substance. These substances are often given by injections (shots). But a newer method is to put the substance in drops and give them under the tongue. This is called sublingual (which means under the tongue) immunotherapy. This treatment is also sometimes called allergy drops. This policy explains when sublingual immunotherapy is medically necessary.

Note: The Introduction section is for your general knowledge and is not to be taken as policy coverage criteria. The rest of the policy uses specific words and concepts familiar to medical professionals. It is intended for providers. A provider can be a person, such as a doctor, nurse, psychologist, or dentist. A provider also can be a place where medical care is given, like a hospital, clinic, or lab. This policy informs them about when a service may be covered.

Use of Oralair®, Grastek®, and Ragwitek®

Contraindications

Contraindications include severe, unstable or uncontrolled asthma; history of any severe local reaction or any severe systemic allergic reaction to sublingual immunotherapy or any severe local reaction to sublingual allergen immunotherapy; and history of eosinophilic esophagitis.

Administration and Dose

- Prescribing information includes a black box warning for severe allergic reactions including anaphylaxis and severe laryngopharyngeal edema. Patients must be prescribed an epinephrine auto-injector and be trained on how to use it.

- Oralair is approved by the Food and Drug Administration (FDA) for patients 10 to 65 years of age. Grastek has been FDA-approved for patients 5 to 65 years of age. Ragwitek has been FDA-approved for patients 18 to 65 years of age.

- Treatment should begin 12 weeks (16 weeks for Oralair) before the expected onset of the allergy-inducing pollen season. Each product is dosed once daily and continued throughout the pollen season (precoseasonal dosing).

- The first dose is administered under the supervision of a physician experienced in diagnosing and treating severe allergic reactions. Subsequent doses may be taken at home.
• For Oralair, dose titration is required in patients 10 to 17 years of age. Titration can be completed over 3 days at home, 100 index of reactivity (IR) on day 1, 2 times 100 IR on day 2, and 3 times 100 IR on day 3. In patients between 18 and 65 years, no dose titration is needed; treatment is initiated at the maintenance dose of 300 IR.

• Grastek and Ragwitek both are initiated at the maintenance dose (2800 bioequivalent allergy unit and 12 Amb a 1 unit, respectively).

Use of Odactra™

Contraindications

Contraindications are as listed above for Oralair, Grastek, and Ragwitek.

Administration and Dose

• Prescribing information includes a black box warning for severe allergic reactions including anaphylaxis and severe laryngopharyngeal edema. Patients must be prescribed an epinephrine autoinjector and be trained on how to use it.

• Odactra is approved by FDA for patients 18 to 65 years of age.

• Odactra is dosed at one 12 SQ-HDM tablet daily. Per FDA, “SQ-HDM is the dose unit for ODACTRA. SQ is a method of standardization of biological potency, major allergen content and complexity of the allergen extract. HDM is an abbreviation for house dust mite.”

• The first dose is administered under the supervision of a physician experienced in diagnosing and treating severe allergic reactions. Subsequent doses may be taken at home.

Pharmacotherapy of Pollen-Induced Allergic Rhinitis

There is general agreement from clinical practice guidelines on the pharmacologic treatment of pollen-induced allergic rhinitis or rhinoconjunctivitis:

• Treatment should be individualized based on symptom severity and duration, comorbidities, patient age, preference (eg, route of administration, tolerance for adverse effects), and previous treatment history
• Measures to increase treatment adherence (eg, shared decision making, consideration of the patient’s school or work schedule, use of a medication calendar or check-off list) are encouraged

• Goals of treatment are symptom reduction and improvements in functional capacity and quality of life

• A “step-up” (if treatment is inadequate) or "step-down" (if symptom relief is achieved with other interventions, eg, avoidance) approach to treatment is recommended

• Allergen avoidance is the first step of treatment but may be unrealistic for some patients

Six medication classes are used to treat allergic rhinitis:

1. H1 antihistamines (oral and intranasal)

2. Corticosteroids (oral [short-course for severe disease] and intranasal)

3. Leukotriene receptor antagonists (oral)

4. Sympathomimetic decongestants (oral and intranasal)

5. Chromones (intranasal)

6. Anticholinergic, ipratropium bromide (intranasal)
   - Treatment should be symptom-specific, eg, oral antihistamines may be less effective for prominent congestion than other treatments; prominent rhinorrhea may respond to intranasal ipratropium; rhinitis-only symptoms may be treated with local (intranasal) rather than systemic (oral) therapy
   - For mild or intermittent symptoms, oral or nasal antihistamine may be considered first-line treatment
   - Newer generation (selective) oral antihistamines are recommended over older (nonselective) antihistamines. Patients with insomnia and pregnant women may prefer older antihistamines because of their sedating effects and longer safety history, respectively
   - Intranasal corticosteroids may be effective for more severe or persistent symptoms
Combination treatment (eg, oral antihistamine plus intranasal corticosteroid, intranasal antihistamine and corticosteroid, antihistamine [oral or intranasal] plus sympathomimetic [oral or short-course (≤5 days to avoid rebound congestion) intranasal]) may be effective for symptoms nonresponsive to single medications.

- Oral sympathomimetics may cause insomnia; their use is limited in patients with certain comorbidities (eg, diabetes, unstable hypertension).
- Oral leukotriene receptor antagonists may reduce asthma exacerbations in patients with comorbid asthma.

Consideration of Age

The ages stated in this policy for which Grastek®, Ragwitek®, Oralair®, and Odactra™ are considered medically necessary are based on the ages approved in the FDA labeling.

Benefit Application

Sublingual immunotherapy may be offered by specialized clinics.

Evidence Review

Description

Sublingual immunotherapy (SLIT) is a potential alternative to subcutaneous immunotherapy (SCIT) for providing allergen-specific therapy. SLIT is proposed as a more convenient alternative delivery route for treating a variety of allergic disorders.

Background

Allergen-specific immunotherapy involves administering well-characterized allergen extracts, the potencies of which are measured and compared with a reference standard. An initial induction or build-up phase progressively increases the allergen dose; this is followed by years of
maintenance injections at the highest dose. Allergen-specific immunotherapy has been used to treat various conditions, including insect allergy, allergic rhinitis, and asthma. Subcutaneous immunotherapy is the standard of care. Due to the inconvenience of multiple injections, particularly in children, alternative delivery routes have been investigated; of these, sublingual immunotherapy is the most prominent. Sublingual immunotherapy targets absorption to the sublingual and buccal mucosa. Allergen preparations used for sublingual immunotherapy are held under the tongue for one to several minutes and then swallowed or spit out.

Summary of Evidence

For individuals who have pollen-induced allergic rhinitis or rhinoconjunctivitis who receive SLIT, the evidence includes RCTs and systematic reviews. Relevant outcomes are symptoms, quality of life, hospitalizations, medication use, and treatment-related morbidity. Three sublingual pollen extracts are approved by FDA for treatment of pollen-induced allergic rhinitis with or without conjunctivitis. Large, well-designed RCTs supporting the marketing applications for these products have provided consistent evidence of efficacy and safety. Although trials were placebo-controlled, rather than SCIT-controlled, minimum clinically important criteria for demonstrating efficacy were prespecified and were met in most studies. The evidence is sufficient to determine that the technology results in a meaningful improvement in the net health outcome.

For individuals who have house dust mite-specific allergy who receive SLIT, the evidence includes RCTs and systematic reviews. Relevant outcomes are symptoms, quality of life, hospitalizations, medication use, and treatment-related morbidity. One sublingual extract is approved by the Food and Drug Administration for treatment of house dust mite-induced allergic rhinitis with or without conjunctivitis. Most RCTs evaluating SLIT for patients with dust mite allergies have been placebo-controlled. Meta-analyses have found high levels of heterogeneity among studies. A more recent meta-analysis, published in 2015, had mixed findings; some outcomes but not others favored SLIT over placebo or pharmacologic treatment. Trials comparing SLIT with SCIT have tended not to find differences in efficacy, but conclusions are limited due to small sample sizes. More recent large, well-designed RCTs supporting the marketing applications for these products have provided consistent evidence of efficacy and safety. Although trials were also placebo-controlled, rather than SCIT-controlled, minimum clinically important criteria for demonstrating efficacy were prespecified and met in the largest studies. The evidence is sufficient to determine that the technology results in a meaningful improvement in the net health outcomes.

For individuals who have food allergy who receive SLIT, the evidence includes RCTs and systematic reviews. Relevant outcomes are symptoms, quality of life, hospitalizations, medication
use, and treatment-related morbidity. A few RCTs have evaluated SLIT for treatment of food allergies, and these studies have had small sample sizes and have tended to be rated as low quality by systematic reviewers. The available RCTs have not consistently found that SLIT is more effective than placebo or oral immunotherapy. No RCTs were identified that compared SLIT with SCIT. The evidence is insufficient to determine the effects of the technology on health outcomes.

**Practice Guidelines and Position Statements**

**American Academy of Otolaryngology–Head and Neck Surgery Foundation**

In 2015, the American Academy of Otolaryngology–Head and Neck Surgery Foundation published clinical practice guidelines on allergic rhinitis that contained the following statement:

Clinicians should offer, or refer to a clinician who can offer, immunotherapy (sublingual or subcutaneous) for patients with AR [allergic rhinitis] who have inadequate response to symptoms with pharmacologic therapy with or without environmental controls.

Recommendation based on RCTs [randomized controlled trials] and systematic reviews, with a preponderance of benefit over harm.

**American Academy of Allergy, Asthma and Immunology et al**

In 2017, the American Academy of Allergy, Asthma, and Immunology (AAAAI) and the American College of Allergy, Asthma, and Immunology jointly published updated practice parameters on sublingual immunotherapy (SLIT). These recommendations apply to use of SLIT agents approved by the Food and Drug Administration at time of publication: 5-grass (Oralair), Timothy grass (Grastek), and ragweed (Ragwitek). Table 1 summarizes statements made.

In 2013, AAAAI and the European Academy of Allergy and Clinical Immunology published a consensus report on allergy immunotherapy. The report summarized the literature and current practices in the United States and Europe; it did not include clinical recommendations. The report concluded: “Allergy immunotherapy (AIT) is effective in reducing symptoms of allergic asthma and rhinitis, as well as venom-induced anaphylaxis. In addition, AIT modifies the underlying course of disease. However, AIT remains a niche treatment secondary to symptomatic drugs because of its cost, long duration of treatment and concerns regarding safety and effectiveness....”

In 2011, a joint task force of the AAAAI, the American College of Allergy, Asthma and Immunology, and the Joint Council of Allergy, Asthma and Immunology issued updated practice parameters for allergen immunotherapy. The document stated that randomized controlled trials of sublingual immunotherapy (SLIT) in patients with allergic rhinitis and asthma have demonstrated significant improvement in symptoms. The authors noted that there were no Food and Drug Administration-approved extract formulations for a noninjection route of immunotherapy.
European Academy of Allergy and Clinical Immunology

In 2018, the European Academy of Allergy and Clinical Immunology published evidence-based guidelines on allergic rhinoconjunctivitis. The EAACI guidelines suggest that both SLIT and subcutaneous immunotherapy are effective for allergic rhinitis (AR), however, there was insufficient data to determine which is more effective. Table 2 summarizes the recommendations for treatment of adults using SLIT.

FDA: Food and Drug Administration; GOE: grade of evidence; LOE: level of evidence; SLIT: sublingual immunotherapy.

In 2014, the European Academy of Allergy and Clinical Immunology published evidence-based guidelines on the diagnosis and management of food allergy. Based on single-arm studies (level III evidence), the guideline authors concluded: “Food allergen-specific immunotherapy for primary food allergy is a promising immunomodulatory treatment approach, but it is associated with risk of adverse reactions, including anaphylaxis; it is therefore not currently recommended for routine clinical use.” Based on expert opinion (level IV evidence), it was recommended: “For patients with respiratory or other allergy symptoms to inhalant allergens that may also cause cross-reactive food allergy, specific immunotherapy is only recommended for the treatment of the respiratory symptoms, not for cross-reactive food allergy.”
World Allergy Organization

In 2013, the World Allergy Organization updated its position paper on SLIT. Evidence-based conclusions included:

- “Grass-pollen sublingual immunotherapy (SLIT) is effective in seasonal allergic rhinitis in children ≥5 years of age.”
- “Grass-pollen SLIT is probably effective in children ≥4 to <5 years of age.”
- “Grass or house dust mite (HDM) SLIT may be used for allergic rhinitis in children with asthma... More large randomized trials are needed...”
- “Use of SLIT for latex allergy, atopic dermatitis, food allergy, and Hymenoptera venom is under investigation; more evidence is needed to support the use of SLIT for these indications”
- “Patients eligible for SLIT should have a ‘history of symptoms related to allergen exposure and a documented positive allergen-specific IgE [immunoglobulin E] test.’”
- “SLIT may be considered as initial treatment ... particularly [for] patients whose allergy is uncontrolled with optimal pharmacotherapy (that is, those who have severe chronic upper airway disease) ... patients in whom pharmacotherapy induces undesirable side effects ... patients who do not want to be on constant or long-term pharmacotherapy.”
- “Failure of pharmacotherapy is not an essential prerequisite for ... SLIT.”

Ongoing and Unpublished Clinical Trials

Some currently unpublished trials that might influence this review are listed in Table 3.

There is no national coverage determination.

Regulatory Status

In April 2014, the first sublingual allergen extract tablets were approved by the U.S. Food and Drug Administration (FDA) through the biologics license application process for treatment of pollen-induced allergic rhinitis with or without conjunctivitis:

- On April 1, FDA approved Oralair® (Stallergenes) allergen extract for patients 10 to 65 years of age. Oralair® contains freeze-dried pollen allergen extracts of 5 grasses: Kentucky Blue Grass, Orchard, Perennial Rye, Sweet Vernal, and Timothy.
On April 11, FDA approved Grastek® (Merck) Timothy grass pollen (Phleum pretense) allergen extract for patients 5 to 65 years of age. (Grastek® is marketed in Europe as Grazax®.)

On April 17, the FDA approved Ragwitek® (Merck) short ragweed pollen allergen extract for patients 18 to 65 years of age.

In March 2017, FDA approved Odactra (Merck) allergan extract for patients 18 to 65 years of age who have house dust mite-induced allergic rhinitis with or without conjunctivitis. Odactra contains freeze-dried extracts of dust mites (Dermatophagoides farinae and Dermatophagoides pteronyssinus).
