Introduction

Genes contain instructions for how a cell makes proteins. Proteins drive the functions within a cell. HER2 (human epidermal growth factor receptor 2) is a gene that can affect the development of breast cancer. About one in four or five cases of breast cancer are caused by the HER2 gene making too many copies of itself. And because too many HER2 genes are being made, too much HER2 protein also is being made. HER2 inhibitors are drugs that block the function of the HER2 protein. They essentially cut off the growth signals to the cancerous cells. This policy discusses when HER2 inhibitors may be considered medically necessary.

Note: The Introduction section is for your general knowledge and is not to be taken as policy coverage criteria. The rest of the policy uses specific words and concepts familiar to medical professionals. It is intended for providers. A provider can be a person, such as a doctor, nurse, psychologist, or dentist. A provider also can be a place where medical care is given, like a hospital, clinic, or lab. This policy informs them about when a service may be covered.

Nerlynx ® (neratinib) may be considered medically necessary for use in advanced or metastatic breast cancer in adult patients with breast cancer whose tumors overexpress or have amplified HER2 protein (HER2-positive breast cancer) when all of the following are true:
- Neratinib is used in combination with capecitabine
- Patient has stage III or IV breast cancer
- Neratinib is used after patient received two or more prior anti-HER2 based regimens in the metastatic setting (stage IV)
- Patient has HER2-positive breast cancer
- The dose is limited to 240 mg (six tablets) per day

**Note:** Total duration of neratinib therapy will be limited to maximum of 1 year when used for extended adjuvant treatment.

**Related Information**

**HER2 Testing**

Appropriate patient selection for trastuzumab therapy is predicated on detection of HER2 overexpression. HER2 overexpression should be assessed only by facilities with demonstrated proficiency in the specific assay being used. Unreliable results may result from improper assay performance. Several assays are commercially available to aid selection of patients for Trastuzumab therapy. These include the HercepTest™ and Pathway® HER2/neu, which are immunohistochemical assays (IHC), and PathVysion® and HER2 FISH pharmDx™, which are fluorescence in situ hybridization assays (FISH).
Unresolved Issues

As discussed in this policy, randomized clinical trials have consistently reported a beneficial effect of adjuvant trastuzumab in conjunction with adjuvant chemotherapy in patients with completely resected HER2-positive breast cancer.

Duration of Therapy

While data support the use of adjuvant trastuzumab for a year, evidence is inadequate to determine if a second year of Trastuzumab therapy increases benefit. This comparison is a focus of the HERA trial, but data from its third arm, given 2 years of trastuzumab, are not yet available.

Starting Trastuzumab Long After Completing Adjuvant Chemotherapy

Trastuzumab was rapidly integrated into the adjuvant therapy of patients with HER2-positive early-stage breast cancer. When the first interim results were reported in 2005, there was interest in offering Trastuzumab to patients who would otherwise meet criteria, but who had already completed adjuvant therapy prior to the announcement of trial results. This group of patients still has not been formally studied, but patients in the HERA trial started Trastuzumab a median 8 months after surgery. At the time, investigators suggested that patients who completed adjuvant chemotherapy within the prior 6 months might be considered reasonable candidates.

Concurrent Versus Sequential Therapy

At present, data are inadequate to determine the optimal regimen of trastuzumab within the overall regimen of adjuvant therapy, specifically whether concurrent or sequential Trastuzumab is preferred. The North Central Cancer Treatment Group N9831 (NCCTG N9831) trial includes two arms given Trastuzumab, one concurrent with and the other following paclitaxel. Results for this comparison have not been published.

The FDA-approved label recommends that left ventricular ejection fraction (LVEF) should be measured before starting trastuzumab therapy and shown to be within the treating institution’s normal range. Continued therapy should depend on periodic monitoring (eg, at 3, 6, and 12 months) without an unacceptable decrease (eg, greater than 15%) from baseline LVEF.
Breast cancer patients considered for preoperative (neoadjuvant or primary systemic) chemotherapy may have early-stage disease, but larger tumors (stages IIA, IIB or operable T3N1M0), or may have locally advanced but non-metastatic (M0) disease.

**Safety Concerns with Ado-Trastuzumab Emtansine**

Although there are no absolute contraindications to ado-trastuzumab emtansine, there are a number of additional safety considerations:

- Ado-trastuzumab emtansine is Pregnancy Category D, is associated with known gestational adverse effects, and should not be used in pregnant women. Effective contraception should be used during and for at least 6 months following treatment.

- Increases in liver function enzymes are common. Dose modifications based on liver function tests are recommended.

- Decreases in left ventricular ejection fraction have been noted. Inclusion criteria for the EMILIA trial included a LV ejection fraction of at least 50% or greater.

- The safety and efficacy of ado-trastuzumab emtansine in pediatric patients has not been established.

- Other safety concerns, which generally do not warrant a change in management, include infusion reactions, pulmonary toxicity, GI symptoms, and fatigue.

**Benefit Application**

State and federal mandates requiring coverage of FDA-approved drugs may supersede this policy.

**Evidence Review**

**Description**

The human epidermal growth factor receptor 2 (HER2) gene located on chromosome 17q, encodes a transmembrane ligand orphan receptor tyrosine kinase that amplifies the signal
provided by other members of the HER family (HER1/EGFR, HER3, and HER4) by forming heterodimers with them. HER2 activation and dimerization causes alterations in several complex downstream-signaling cascades that are involved in regulation of cell growth, proliferation, migration, adhesion, and survival, and thus has been implicated in oncogenesis.

The HER2 gene is amplified and overexpressed in 20–30% of breast cancers, a finding which has been associated with more aggressive disease and higher relapse and mortality rates. HER2 is also overexpressed in other epithelial cancers, including ovarian, thyroid, lung, salivary gland, stomach, colon, and prostate, making it a logical target for antibody-mediated therapy.

Trastuzumab has only received U.S. Food and Drug Administration (FDA) marketing approval for specific patients with breast cancer. However, its activity has been investigated in the preoperative (neoadjuvant) setting for breast cancer, in combination with regimens besides those specified in the FDA-approved product label, and in a wide range of other types of cancer that overexpress HER2.

**Herceptin® (trastuzumab) in Breast Cancer**

**Metastatic**

The initial 1998 approval by the FDA for trastuzumab in metastatic breast cancer was based on results from 2 pivotal clinical trials. In one trial, single-agent trastuzumab was given to women (n=222) who had received 1 or 2 courses of cytotoxic chemotherapy, yielding an objective response rate (ORR) of 15% and a median duration of response of 9.1 months.1 In a second randomized trial (n=469), trastuzumab was evaluated as part of a first-line combination regimen consisting of either doxorubicin (A) plus cyclophosphamide (C) or paclitaxel (P).2 The addition of trastuzumab to chemotherapy resulted in an increased response rate (50% vs. 32%, p<0.001), longer median response duration (9.1 vs. 6.1 months, p<0.001), and prolonged overall survival (OS) (25.1 months vs. 20.3, p=0.046) compared to chemotherapy alone. Because a significantly higher incidence of New York Heart Association (NYHA) class III or IV cardiotoxicity was reported in this trial among patients who received AC plus trastuzumab, compared to AC, paclitaxel/trastuzumab, or paclitaxel, the FDA and others subsequently cautioned against using a regimen that combined trastuzumab with doxorubicin.3,4

Similar efficacy results have been subsequently reported with the combination of trastuzumab with docetaxel (D) in 188 patients with metastatic breast cancer.5 Further studies of other trastuzumab combination regimens have included its use with capecitabine, vinorelbine, gemcitabine, and platinum salts, achieving response rates ranging from 27% to 86%.6,7 These
early studies also have shown that trastuzumab can be combined with non-approved chemotherapy regimens while adding little to the overall toxicity profile in the metastatic setting. Similarly, trastuzumab is being evaluated in combinations with hormonal modalities such as tamoxifen or aromatase inhibitors.

Kaufman and colleagues reported the results of the first randomized Phase III trial combining a hormonal agent (aromatase inhibitor anastrozole) and trastuzumab without chemotherapy. Patients were postmenopausal with HER2 and hormone receptor-positive metastatic disease (patients with CNS metastases were excluded). Patients were randomized to receive trastuzumab plus anastrozole (n=103) or anastrozole alone (n=104). Baseline characteristics were balanced between the two groups. The primary endpoint was progression free survival (PFS), defined as the time from randomization and the date of disease progression or death. There were a total of 187 withdrawals from the trial treatment, most frequently due to progressive disease. In the anastrozole-only arm, 70% of the patients who experienced progressive disease subsequently crossed over to receive a trastuzumab containing regimen. Progression free survival was significantly improved in the trastuzumab plus anastrozole arm with a median PFS of 4.8 months (95% confidence interval [CI]: 3.7 to 7.0 months) versus 2.4 months (95% CI: 2.0 to 4.6 months) in the anastrozole-only arm (hazard ratio [HR] =0.63; 95%CI: 0.47-0.84; p=0.0016). Grade 3 and 4 adverse events were 23% and 5%, respectively, in the trastuzumab plus anastrozole arm, and 15% and 1% in the anastrozole-only arm.

Von Minckwitz and colleagues investigated whether trastuzumab should be given beyond disease progression in women with HER2-positive locally-advanced or metastatic breast cancer. Patients were randomly assigned to chemotherapy (capecitabine) alone (n=78) or to capecitabine plus trastuzumab (n=78). Follow-up was 15.6 months, during which time there were 38 deaths in the capecitabine arm versus 33 in the capecitabine plus trastuzumab group. The primary end point in the study was time to progression, which was defined as the time period between randomization and documented disease progression or disease-related death. Median times to progression were 5.6 months in the capecitabine group and 8.2 months in the combined therapy group; hazard ratio 0.69 (95% CI: 0.48 to 0.97; p=0.0338). Differences in OS were not significant at 20.4 months (95% CI: 17.8 to 24.7) in the capecitabine group and 25.5 months (95% CI: 19.0 to 30.7) in the combined therapy group (p=0.257).

**Adjuvant**

Results from randomized trials provide data on clinical outcomes of adjuvant trastuzumab therapy: the Breast Cancer International Research Group 006 trial (BCIRG 006, n=3,222); the Herceptin Adjuvant Trial (HERA, n=5,090); the North Central Cancer Treatment Group N9831
trial (NCCTG N9831, n=3,505)\(^{12}\); the North American National Surgical Adjuvant Breast and Bowel Project B31 trial (NSABP B31, n=2,030)\(^{13}\); and, the Finnish Herceptin Study (FinHer, n=232)\(^{14}\). All women enrolled in these studies tested positive for HER2 using either immunohistochemical assays (IHC) or fluorescence in situ hybridization assays (FISH) assays. There were important differences in patient characteristics, trial design, and implementation, as reviewed in depth elsewhere.\(^{7,15-18}\) Table 1 summarizes the design and results of those trials.

Despite substantial differences in trial design and patient characteristics, the latest available data from adjuvant trials of trastuzumab demonstrate consistent, clinically significant improvements in DFS. The combined analysis of the NSABP B31, NCCTG N9831, BCIRG, and HERA trials show significant improvement in OS versus controls in patients given adjuvant trastuzumab. Although only HERA reported that trastuzumab improved DFS in a subgroup with high-risk, node-negative disease, 3 other trials included similar patients and found better outcomes in the trastuzumab arm. While few patients were node negative in NCCTG N9831 and FinHer, 29% of each arm was node negative in BCIRG 006. Note that all trials excluded patients with small (<1 cm) node-negative tumors. Thus, there is no evidence that adjuvant trastuzumab benefits this subgroup of HER2-positive patients. The benefits of trastuzumab were independent of estrogen-receptor status or the type of prior chemotherapy. These data do not settle the issue of optimal timing and duration of trastuzumab therapy, but data from the FinHer study suggest that even a short course (9 weeks) may be beneficial in reducing the risk of recurrence and death in women with HER2-positive, early-stage disease. Furthermore, final results for the 2-year trastuzumab regimen arm in HERA are not yet available.

Grade III/IV congestive heart failure (CHF) or cardiac-related death for patients receiving trastuzumab-containing adjuvant regimens ranged from 0 (FinHer) to 4.1% (NSABP B31) overall, with age and baseline left-ventricular ejection fraction related to the risk for cardiac dysfunction. Concurrent use of trastuzumab and a taxane following 4 cycles of AC resulted in the highest rates of CHF (1.5%, 2.4%, and 3.4% for the BCIRG, N9831, and B31 trials, respectively). Sequential administration of anthracyclines, taxanes, and trastuzumab resulted in CHF rates of 1.4% and 0.5% for the N9831 and HERA trials, respectively. The non-anthracycline arm of the BCIRG trial had the lowest rate (0.3%) of CHF. While the acceptable rate of cardiac events overall was likely related to rigorous monitoring during the trials, cross-trial comparisons and conclusions are
difficult due to differences in definitions of cardiac events, evaluations for cardiac safety, analysis of cardiac endpoints (cumulative vs. overall incidence) and duration of follow-up.

**Neoadjuvant**

A randomized, controlled trial has been published on the benefits of adding trastuzumab to neoadjuvant chemotherapy.¹⁹ The study sequentially administered two neoadjuvant chemotherapy regimens followed by surgery to breast cancer patients with stage II to IIIA disease and compared paclitaxel (four 3-week cycles) followed by fluorouracil, epirubicin, and cyclophosphamide (FEC; four 3-week cycles) with versus without trastuzumab. A data monitoring committee ended the trial after investigators randomized 42 patients, when a requested (but unplanned) analysis showed pathologic complete response (pCR) rates of 25% in the arm without and 66.7% in the arm with trastuzumab. Approximately the same proportion of patients in each arm (52.6% without and 56.5% with trastuzumab) received breast-conserving surgery, but patient choice likely influenced these results. A subsequent report of the same study included longer follow-up for randomized patients, and additional nonrandomized patients.²⁰ Results showed pCR in 26.3% (95% CI: 9–51%) of 19 patients randomized to neoadjuvant chemotherapy without trastuzumab, 65.2% (95% CI: 43–84%) of 23 patients randomized to the same neoadjuvant regimen plus trastuzumab, and 54.5% (95% CI: 32.2–75.6%) of 22 consecutive nonrandomized patients also given the same regimen plus trastuzumab.²⁰ At a median follow-up of 36.1 months for randomized patients, 3 in the chemotherapy-only arm experienced recurrence (1 of whom died), and none in the arm with added trastuzumab.

Although few recurrences or deaths have occurred thus far in this terminated randomized, controlled trial, the 2-fold increase in pCR rate is unlikely to be a chance result.¹⁹,²⁰ Analyses from randomized, controlled trials²¹-²³ and single-arm studies²⁴-²⁶ showed that patients with pCR after neoadjuvant chemotherapy (determined postoperatively) had significantly longer overall, disease-free, and/or recurrence-free survival than those who did not achieve pCR. This also was true when those who achieved pCR were compared with those who achieved clinically complete responses but were subsequently shown by postoperative pathology to have residual (microscopic) invasive disease. Thus, improving pCR rate by adding trastuzumab to neoadjuvant chemotherapy for HER2 patients with high-risk, larger tumors predicts improved overall and disease-free survival.

Additional reasoning supports considering neoadjuvant trastuzumab medically necessary for HER2-positive patients undergoing neoadjuvant chemotherapy, even if the one available randomized, controlled trial did not show it increased the proportion of patients given breast-
conserving surgery. When used to reduce risk of recurrence for patients with operable breast cancer, chemotherapy is either completed before surgery or not begun until after. Those given preoperative chemotherapy rarely receive additional chemotherapy after resection, unless their breast cancer recurs or progresses. Although hormone-receptor-positive patients given neoadjuvant chemotherapy are given tamoxifen or an aromatase inhibitor after resection, most HER2-positive patients are hormone-receptor negative and would not receive hormone therapy. Whether chemotherapy is used pre- or postoperatively, it is given for 18-24 weeks depending on the regimen and trastuzumab currently is given for a full year. Trastuzumab administration was initiated concurrently with chemotherapy in most trials on adjuvant therapy. Consequently, it seems reasonable to initiate trastuzumab with chemotherapy for HER2-positive patients receiving neoadjuvant chemotherapy.

**Herceptin® (trastuzumab) in Non-Breast Cancer**

**Gastric Cancer**

One Phase II and one Phase III trial have been reported on the use of trastuzumab in advanced gastric cancer; the Phase II trial is published in abstract form only. Cortés-Funes and colleagues reported preliminary results of a Phase II study of 21 patients with advanced gastric cancer with overexpression/amplification of HER2.27 Patients received trastuzumab in combination with chemotherapy (cisplatin) every 21 days until disease progression, unacceptable toxicity or withdrawal. Seventeen of the 21 patients were evaluable. Efficacy was reported as: 6 (35%) patients achieved response (1 CR, 5 PR), 3 (17%) had disease stabilization, 4 patients progressed and for 4 patients it was too early to report. The authors concluded that trastuzumab plus cisplatin is a well-tolerated regimen with promising activity in HER2/neu overexpressing gastric cancer.

Van Cutsem and colleagues reported the results of a Phase III, open-label, randomized, multicenter (122 centers in 24 countries) trial in which patients with HER2-positive, locally advanced, recurrent, or metastatic gastroesophageal or gastric adenocarcinoma received chemotherapy consisting of capecitabine plus cisplatin or fluorouracil plus cisplatin with or without trastuzumab.28 Patients who received the trastuzumab were given it every three weeks for 6 cycles, until disease progression. The primary endpoint of the study was overall survival; secondary endpoints were overall response rate (ORR), PFS, time to progression, duration of response and safety. Median follow-up was 18.6 months in the chemotherapy plus trastuzumab group and 17.1 months in the chemotherapy-alone group. Tumors from 3,807 patients were tested for HER2 status; 22.1% were positive. Five-hundred ninety-four patients were randomized
to the 2 treatment arms. Median OS for the group that received trastuzumab compared to those that did not was 13.8 months (95% CI: 12-16) versus 11.1 months (95% CI: 10-13) (p=0.0046; HR 0.74; 95%CI 0.60-0.91). ORR was 47.3% for those that received trastuzumab versus 34.5% for those that did not (p=0.0017). Rates of overall grade 3 or 4 adverse events (201 [68%] versus 198 [68%]) and cardiac adverse events (17 [6%] versus 18 [6%]) did not differ between the chemotherapy and trastuzumab versus chemotherapy alone groups.

Prostate Cancer

Uncontrolled pilot studies have reported preliminary results for outcomes of trastuzumab combined with chemotherapy for advanced androgen-dependent or androgen-independent prostate cancer\textsuperscript{29,30} that is positive for HER2 overexpression or amplification. A study of trastuzumab and docetaxel for HER2-positive prostate cancer was closed as not feasible, since only 7 of 100 patients screened had 2+ or 3+ HER2 expression by immunohistochemistry, as required for study eligibility.\textsuperscript{31} Another study reported treatment with trastuzumab as a single agent demonstrated poor efficacy in 18 patients with advanced hormone-refractory prostate cancer.\textsuperscript{32}

Salivary Gland Cancer

A study to evaluate the use of trastuzumab in salivary gland cancer was closed early after it was found that the majority of salivary gland tumors did not overexpress HER2.\textsuperscript{33}

Ovarian and Peritoneal Cancer

A study of trastuzumab in patients with recurrent or refractory ovarian or primary peritoneal carcinoma found a low rate of clinical response to treatment.\textsuperscript{34}

Non-Small Cell Lung Cancer

Three reports were identified from phase II trials of trastuzumab plus chemotherapy to treat non-small cell lung cancer.\textsuperscript{35-37} Each of these studies reported that the addition of trastuzumab did not improve outcomes.
A randomized Phase II comparison of docetaxel plus trastuzumab versus paclitaxel plus trastuzumab in chemotherapy-naive non-small cell lung cancer patients (n=65) reported no differences in objective response rates, median survival, or toxicity between arms.

**Esophageal Cancer**

Median OS was 24 months in an uncontrolled Phase I/II study (n=19) that combined trastuzumab with paclitaxel, cisplatin, and radiation for locally advanced, HER2 overexpressing esophageal cancer.

**Bladder and Kidney Cancer**

Two uncontrolled small series were also reported on trastuzumab for metastatic transitional cell cancer of the bladder (n=7) or bladder and renal pelvis (n=6). A Phase II trial that treated 44 patients with HER2–positive, advanced urothelial carcinoma with a combination of trastuzumab, paclitaxel, carboplatin, and gemcitabine, showed 31 (70%) patients responded, including 5 complete and 26 partial responses. Median time to progression and survival were 9.3 and 14.1 months, respectively. However, the study lacked controls given the same chemotherapy without trastuzumab.

**Summary**

Targeted therapy using trastuzumab against human epidermal growth factor receptor type-2 (HER2) has shown survival benefit for primary and metastatic breast cancer and has become the accepted and usual therapy for patients with HER2 positive breast cancer.

One Phase III trial has reported outcomes with the use of trastuzumab in advanced gastric or gastroesophageal cancer, with a 2-month OS benefit in the trastuzumab arm and no difference in severe adverse events between the group that received chemotherapy plus trastuzumab versus chemotherapy alone.

Studies examining the possible uses of trastuzumab in HER2-positive cancers other than breast and gastric/gastroesophageal cancers have consisted mainly of small uncontrolled series. For the most part, results have been disappointing, with little to no improvement in outcomes; studies have also suffered from the low percentage of HER2 overexpression in certain tumors.
**Tykerb® (lapatinib)**

The efficacy and safety of Tykerb® (lapatinib) in combination with capecitabine in breast cancer were evaluated in a randomized, Phase III trial. Patients eligible for enrollment had HER2 (ErbB2) over-expressing (IHC 3+ or IHC 2+ confirmed by FISH), locally advanced or metastatic breast cancer, progressing after prior treatment that included anthracyclines, taxanes, and trastuzumab.

Patients were randomized to receive either lapatinib 1,250 mg once daily (continuously) plus capecitabine 2,000 mg/m2/day on Days 1-14 every 21 days, or to receive capecitabine alone at a dose of 2,500 mg/m2/day on Days 1-14 every 21 days. The endpoint was time to progression (TTP). TTP was defined as time from randomization to tumor progression or death related to breast cancer. Based on the results of a pre-specified interim analysis, further enrollment was discontinued. Three hundred ninety-nine (399) patients were enrolled in this study. The median age was 53 years and 14% were older than 65 years. Ninety-one percent (91%) were Caucasian. Ninety-seven percent (97%) had stage IV breast cancer, 48% were estrogen receptor+ (ER+) or progesterone receptor+ (PR+), and 95% were ErbB2 IHC 3+ or IHC 2+ with FISH confirmation. Approximately 95% of patients had prior treatment with anthracyclines, taxanes, and trastuzumab. Independent assessment of patients showed a median time to progression of 27.1 weeks in the lapatinib group vs. 18.6 weeks in controls. Response rates were 23.7% (95% CI 18.0-30.3) and 13.9% (95% CI 9.5-19.5), respectively (HR 0.57, 95% CI 0.43-0.77, p=0.00013).

**Kadcyla™ (ado-trastuzumab emtansine)**

Based on a literature search performed through April 2018, the evidence that was identified for this policy review consists of one RCT that was performed in support of application for FDA-approval, and two uncontrolled studies.

**Randomized, Controlled Trial**

The Phase III EMILIA trial (N=991) was a randomized, stratified, active- controlled, open-label trial conducted in 26 countries (27% US). Patients had unresectable, locally advanced or metastatic HER2-positive breast cancer previously treated with trastuzumab and a taxane. Median age was 53 years, approximately 37% of patients had three or more metastatic sites, and 68% had visceral disease involvement. Patients were stratified (by world region, number of prior chemotherapy regimens for advanced disease, and visceral disease involvement) and
randomized to one of two treatment groups: intravenous infusions of ado-trastuzumab emtansine 3.6 mg/kg every 21 days or self-administered oral lapatinib 1250 mg daily plus oral capecitabine 1000 mg/m² every 12 hours for the first 14 days of each 21-day treatment cycle. Potential bias introduced by the open-label trial design was minimized by assessor blinding of PFS and tumor response endpoints and using an easily measured endpoint, OS.

Primary efficacy outcomes were PFS by independent review committee and overall survival (OS). PFS was 9.6 months in the ado-trastuzumab emtansine group and 6.4 months in the lapatinib + capecitabine group (hazard ratio [HR] 0.65 [95% CI: 0.55, 0.77]). Statistically nonsignificant differences in PFS were found in patients without visceral involvement and in patients from Asia and other parts of the world (stratified subgroups) and in patients 65 to 74 years of age and patients without measurable disease at baseline (prespecified subgroups). At a median follow-up of approximately 19 months, an interim analysis of OS crossed the pre-determined stopping boundary, and the trial was discontinued. OS was 30.9 months in the ado-trastuzumab emtansine group and 25.1 in the lapatinib + capecitabine group (HR 0.68 [95% CI: 0.55, 0.85]).

**Uncontrolled Trials**

Two single-arm, open-label, Phase II studies conducted in the US enrolled patients with HER2 positive metastatic breast cancer and measurable disease. In TDM4374g (N=110), patients were previously treated with trastuzumab, lapatinib, a taxane, an anthracycline, and capecitabine. Ninety-eight percent of patients were female, median age was 53 years, 74% of patients had three or more metastatic sites, and patients had received a median of 7 systemic treatments for metastatic disease. In TDM4258g (n=112), patients were previously treated with HER2-directed therapy (trastuzumab or lapatinib). Median age was 55 years, 75% of patients had three or more metastatic sites, and patients had received a median of 5 systemic treatments for metastatic disease. All patients in both studies received ado-trastuzumab emtansine 3.6 mg/kg IV every 3 weeks with dose modifications for adverse events.

Objective response rate (ORR, defined as complete responses plus partial responses) by independent radiologic facility (IRF) was the primary efficacy outcome in both studies. In TDM4374g (more pre-treatment), ORR was 35% (95% confidence interval [CI]: 26, 44). In TDM4258g (less pre-treatment), ORR was 26% (95% CI: 18, 34). There were no complete responses. Median progression-free survival (PFS), a secondary outcome, was 6.9 months (95% CI: 4.2, 8.4) in TDM4374g and 4.6 months (95% CI: 3.9, 8.6) in TDM4258g.
Off-Label Use

Conference abstracts have presented results of several Phase I and Phase II studies of ado-trastuzumab emtansine for off-label uses. The main categories for off-label uses are for breast cancer at earlier stages or in various combination therapies for breast cancer, and for use in non-breast cancers.

Earlier Stages of Breast Cancer

The MARIANNE trial, currently in progress, is a Phase III, three-arm trial comparing ado-trastuzumab emtansine, ado-trastuzumab emtansine plus pertuzumab, and trastuzumab plus a taxane for first-line treatment of metastatic breast cancer. GDC-0941 is an oral inhibitor of a downstream intracellular pathway regulated by HER2. Constitutive activation of this pathway is thought to contribute to trastuzumab insensitivity in HER2-positive breast cancer. A Phase Ib dose escalation study of this combination in patients with HER2-positive breast cancer who progressed on prior trastuzumab therapy is currently in progress.

Additional indications being studied include initial treatment of metastatic breast cancer, in combination with pertuzumab and/or paclitaxel for previously treated metastatic disease, or in patients previously treated with systemic chemotherapy.

Other Cancer Types

In preclinical studies of gastric cancer, ado-trastuzumab emtansine has shown efficacy. An ongoing Phase I study is assessing the combination of ado-trastuzumab emtansine plus capecitabine in patients with metastatic HER2-positive gastric cancer. A Phase III trial (N=412) comparing two different doses of ado-trastuzumab emtansine (3.6 mg/kg every three weeks or 2.4 mg/kg weekly) to standard taxane therapy in patients with HER2-positive advanced gastric cancer who experienced disease progression during or after first-line therapy is currently in progress.

Nerlynx ® (neratinib)

In the multicenter, randomized, double-blind, placebo-controlled phase-3 ExteNET, the efficacy of 12 months of neratinib were evaluated in stage 1-3 HER-2 positive breast cancer. Patients
received either neratinib 240mg daily for 12 months or a matching placebo following after trastuzumab-based adjuvant therapy. The results reported that at 2-year follow-up, the neratinib group had significantly fewer invasive disease-free survival events vs. the placebo group (70 vs. 109 events, HR 0.67, P=0.0091). The disease-free survival events include local/regional invasive recurrence and/or distant recurrence to at least one other location/tissue, and death. The neratinib group also had higher 2-year invasive disease-free survival rate (93.9% vs. 91.6%, P=0.0091), higher 2-year rates for distant disease-free survival (95.1% vs. 93.7%), and longer time to distant recurrence (95.4% vs. 93.9%). Overall survival data were not mature but would continue to be monitored. Other trials included in the support for FDA-approved labeling are two phase-2 studies to establish the efficacy and safety of neratinib as compared to the current standard therapy (neratinib + paclitaxel vs. trastuzumab + paclitaxel, neratinib monotherapy vs. lapatinib + capecitabine) in HER2-positive BC.

Other HER2 Inhibitors

Tykerb® (lapatinib) is a small molecule 4-anilinoquinazoline kinase inhibitor of the intracellular tyrosine kinase domains of both Epidermal Growth Factor Receptor (EGFR [ErbB1]) and of Human Epidermal Receptor Type 2 (HER2 [ErbB2]) receptors. Lapatinib inhibits ErbB-driven tumor cell growth in vitro and in various animal models.

Lapatinib is indicated for use in combination with capecitabine for the treatment of patients with advanced or metastatic breast cancer whose tumors overexpress HER2 and who have received prior therapy including an anthracycline, a taxane, and trastuzumab.

Perjeta® (pertuzumab) is a HER dimerization inhibitor recently approved by the FDA for use in combination with trastuzumab and docetaxel in patients with HER2-positive metastatic cancer who are treatment naïve or whose disease has recurred after adjuvant therapy.

Kadcyla™ (ado-trastuzumab emtansine), also known as trastuzumab-DM1 or T-DM1, is an antibody-drug conjugate comprising trastuzumab and emtansine (DM1). It is a HER2 antagonist that is intended as treatment for patients with breast cancers that overexpress HER2, and it may also have applications for other HER-2 positive malignancies. Emtansine (previously called “DM1” for “derivative of maytansine 1”) is a sulfur-containing derivative of the potent microtubule inhibitor, maytansine. Emtansine is conjugated to trastuzumab by lysine side chains, forming a stable thioether linkage. T-DM1 binds HER2 with an affinity comparable to that of trastuzumab. Once internalized, proteolytic degradation of the linker releases both trastuzumab and the active metabolite, maleimidomethyl cyclohexane-1-carboxylate (MCC)-emtansine. MCC-emtansine contains both positive and negative charges and therefore does not readily cross...
plasma membranes, maintaining intracellular concentrations. Ado-trastuzumab emtansine has been shown to preserve the antitumor activity of trastuzumab (described above). Death of HER2-expressing cells therefore results from effects of both active moieties of ado-trastuzumab emtansine.

2012 Update

Updated to include new data on expanded indications of trastuzumab and addition of criteria for pertuzumab.

2013 Update

Updated to include ado-trastuzumab emtansine, which was recently approved by the FDA, and current NCCN Compendium recommendations.

2014 Update

Updated to include current NCCN Compendium recommendations for use of trastuzumab outside of breast cancer.

2015 Update

No information was found that would prompt a change in policy statements.

2018 Update

Updated per labeled indications and literature search from 1/1/17 through 4/1/18.

2019 Update

Reviewed all FDA-approved indications for drugs in policy and made an additional update to Tykerb® criteria to clarify Tykerb® is to be used in combination with capecitabine for the
treatment of HER2-positive breast cancer patients in patients with advanced or metastatic disease.

2020 Update

Reviewed all FDA-approved indications for drugs in policy and no new information was identified that required changes to policy statements. Updated Evidence Review section of policy removing outdated NCCN recommendations.

Regulatory Status

Herceptin® (trastuzumab) is a humanized monoclonal antibody against the extracellular domain of HER2. Trastuzumab has received FDA marketing approval for treatment of HER2-positive breast cancer in both the adjuvant and metastatic settings. It first received FDA approval in September 1998 for use in metastatic breast cancer, as a first-line therapy in combination with paclitaxel and as a single agent in second- and third-line therapy.

In November 2006, trastuzumab received FDA marketing approval as part of a treatment regimen containing doxorubicin, cyclophosphamide, and paclitaxel (AC→P) for the adjuvant treatment of HER2-positive, node-positive early-stage breast cancer.

In January 2008, FDA granted marketing approval for trastuzumab as a single agent for the adjuvant treatment of early stage HER2-positive node-positive breast cancer or node-negative (ER/PR-negative or with one high-risk feature) disease following multi-modality, anthracycline-based therapy. Trastuzumab also was approved to be administered as a single agent in an every-3-week dosing schedule for 1 year.

In May 2008, the FDA approved two new trastuzumab containing regimens for the adjuvant treatment of early-stage HER2-positive node-positive or node-negative (ER/PR-negative or with one high-risk feature) breast cancer. The first regimen is in combination with docetaxel and carboplatin (also known as TCH for Taxotere®, carboplatin, and Herceptin®), which does not contain an anthracycline (doxorubicin) component. The second is part of a treatment regimen containing anthracycline (doxorubicin), cyclophosphamide, and docetaxel (AC-TH).

</tr>
<tr>
<td>08/08/06</td>
<td>Replace Policy - Policy reviewed with literature search; no change to policy statement.</td>
</tr>
<tr>
<td>10/09/07</td>
<td>Replace Policy - Policy reviewed with literature search. New FDA labeled indication noted in the Description. References added. No change to policy statement.</td>
</tr>
<tr>
<td>10/14/08</td>
<td>Replace Policy - Policy reviewed with literature search. Policy no longer addresses only off-label uses. Renamed “HER2 Inhibitors”. Tykerb added as medically necessary when criteria are met. References and code added. Policy guidelines now state that HER2 overexpression testing is required.</td>
</tr>
<tr>
<td>12/08/09</td>
<td>Replace Policy - Policy reviewed with literature search. New indication: Herceptin is now considered medically necessary for gastric cancer.</td>
</tr>
<tr>
<td>05/11/10</td>
<td>Replace Policy - Herceptin, previously considered investigation for esophageal cancer, is now considered medically necessary.</td>
</tr>
<tr>
<td>05/10/11</td>
<td>Replace Policy - Policy rewritten and revised. Title changed from “HER-2 Inhibitors” to “Trastuzumab and Other HER2 Inhibitors.” Components of BC.5.01.12 Trastuzumab incorporated in large part into the policy with the following variations: Lapatinib indications added. ICD-10 codes added to policy.</td>
</tr>
<tr>
<td>12/19/11</td>
<td>Related Policies section updated; policy 2.04.76 added.</td>
</tr>
<tr>
<td>06/26/12</td>
<td>Replace policy. Policy reviewed with literature search; no change in policy statements.</td>
</tr>
<tr>
<td>09/21/12</td>
<td>Coding Section updated – ICD-10 codes are now effective 10/01/2014.</td>
</tr>
<tr>
<td>11/13/12</td>
<td>Replace policy. Policy updated with new data on expanded indications of trastuzumab, coverage is expanded for adjuvant treatment of HER2 positive as either part of several different combination therapy regimens or as a single agent following prior chemotherapy; addition of criteria for pertuzumab; and treatment of HER2 positive metastatic breast cancer in either combination therapy or as a single agent. A medically necessary policy statement has been added for pertuzumab in the treatment of previously untreated HER2-positive breast cancer or recurrent breast cancer after adjuvant therapy, when used in combination with trastuzumab and docetaxel; all other uses are now indicated as investigational.</td>

<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>01/04/13</td>
<td>Minor update. For clarification and improved readability, the medically necessary policy statement for Pertuzumab now appears within the section addressing HER-2 positive breast cancer. No changes have been made to the policy.</td>
</tr>
<tr>
<td>07/08/13</td>
<td>Replace Policy. Added Policy statements and Policy Guidelines information for ado-trastuzumab emtansine. Added clinical trial info for ado-trastuzumab emtansine to the Rationale section. Updated with current NCCN for all 3 drugs.</td>
</tr>
<tr>
<td>03/27/14</td>
<td>Coding update; HCPCS code J9306, effective 1/1/14, added to the policy.</td>
</tr>
<tr>
<td>11/10/14</td>
<td>Annual Review. Updated to include two medically necessary statements from current NCCN Compendium recommendations for use of trastuzumab outside of breast cancer. Codes removed with the exception of HCPCS J0306 and J9355; others are not utilized in adjudication of the policy.</td>
</tr>
<tr>
<td>02/10/15</td>
<td>Minor update. Clarification added to the medically necessary policy statement for pertuzumab: This includes use as adjuvant therapy, neoadjuvant therapy, and treatment of metastatic disease.</td>
</tr>
<tr>
<td>09/08/15</td>
<td>Annual Review. Policy updated with literature review. No change in policy statements.</td>
</tr>
<tr>
<td>01/28/16</td>
<td>Minor update. Added HCPCS code J9354, effective 1/1/16, to the coding table.</td>
</tr>
<tr>
<td>10/01/16</td>
<td>Annual Review, approved September 13, 2016. Clarification on the criteria for pertuzumab (addition of paclitaxel).</td>
</tr>
<tr>
<td>06/01/17</td>
<td>Annual Review, approved May 23, 2017. A statement outlining the length of therapy for initial approval has been added to the policy.</td>
</tr>
<tr>
<td>02/01/18</td>
<td>Interim Review, approved January 9, 2018. Revised Nerlynx (neratinib) criteria to reflect NCCN guidelines.</td>
</tr>
<tr>
<td>04/01/18</td>
<td>Interim Review, approved March 13, 2018. Updated Perjeta criteria to include expanded FDA label indication.</td>
</tr>
<tr>
<td>06/01/18</td>
<td>Annual Review, approved May 3, 2018. Updated references and per labeled indications and literature search, April 2018.</td>
</tr>
<tr>
<td>04/01/19</td>
<td>Interim Review, approved March 12, 2019. Added criteria for Herceptin Hylecta (trastuzumab and hyaluronidase-oysk). Added criteria for Herzuma (trastuzumab-pkrb) and Ontruzant (trastuzumab-dttb) which are both biosimilars of Herceptin (trastuzumab). Added references 67-69. Added HCPCS code J3590.</td>
</tr>
<tr>
<td>05/01/19</td>
<td>Annual Review, approved April 9, 2019. Added criteria for Trazimera (trastuzumab-qyyp) which is a biosimilar to Herceptin (trastuzumab). Updated criteria for Tykerb (lapatinib).</td>
</tr>
<tr>
<td>07/01/19</td>
<td>Coding update, added new HCPCS codes J9356, Q5112, Q5113, Q5114, and Q5115 (new codes effective 7/1/19).</td>
</tr>

</tr>
<tr>
<td>08/01/19</td>
<td>Interim Review, approved July 9, 2019. Added criteria for Kanjinti (trastuzumab-anns) and Ogivri (trastuzumab-dkst) which are biosimilars to Herceptin (trastuzumab). Updated criteria for Kadcyla (ado-trastuzumab emtansine). Updated criteria for Herceptin (trastuzumab) and the trastuzumab biosimilars when used for conditions other than HER2-positive breast cancer. Removed HCPCS code QS115.</td>
</tr>
<tr>
<td>10/01/19</td>
<td>Coding update, added HCPCS codes QS116 and QS117 (new codes effective 10/1/19).</td>
</tr>
<tr>
<td>01/01/20</td>
<td>Interim Review, approved December 17, 2019, effective April 3, 2020. Added Trazimera as first-line with Herceptin.</td>
</tr>
<tr>
<td>08/01/20</td>
<td>Interim Review, approved July 14, 2020. Updated Perjeta to allow coverage with trastuzumab biosimilars and removed for early breast cancer treatment reference to cancer diameter and high risk of recurrence. For Nerlynx (neratinib) added a dose limit of 240 mg (six tablets) per day. Added coverage criteria for Phesgo (pertuzumab, trastuzumab, and hyaluronidase-zzxf) for the treatment of breast cancer. Add J3590 for Phesgo™.</td>
</tr>
<tr>
<td>03/01/21</td>
<td>Interim Review, approved Feb. 9, 2021. Added generic lapatinib to policy with same covered indications as Tykerb (lapatinib). Updated Tykerb (lapatinib) coverage criteria removing two non-FDA approved indications for adjuvant treatment of HER2-positive breast cancer (node positive or negative) as part of several different combination therapy regimens following prior chemotherapy and for treatment of HER2-positive metastatic breast cancer in combination therapy. Added requirement to Tykerb to require generic lapatinib first and placed a dose limit of 1,500 mg per day. Added a new indication to Enhertu (fam-trastuzumab deruxtecan-nxki) for the treatment of gastric or GEJ adenocarcinoma. Added coverage criteria for Margenza (margetuximab-cmkb) for the treatment of metastatic HER2-positive breast cancer. Added HCPCS code J3590.</td>
</tr>
<tr>
<td>04/01/21</td>
<td>Update Related Policies. Policy 2.04.76 archived and references removed.</td>
</tr>
