Introduction

The prostate gland is found only in men and produces some of the fluid that makes up semen. The gland is below the bladder. An enlarged prostate and prostate cancer are two separate conditions. An enlarged prostate is a prostate that simply gets bigger as a man ages. Prostate cancer arises from prostate cells that grow uncontrollably. There are several ways of treating prostate cancer. This policy describes when certain drugs may be covered to treat prostate cancer that doesn’t respond to medication or hormone therapy and has spread to other parts of the body.

Note: The Introduction section is for your general knowledge and is not to be taken as policy coverage criteria. The rest of the policy uses specific words and concepts familiar to medical professionals. It is intended for providers. A provider can be a person, such as a doctor, nurse, psychologist, or dentist. A provider also can be a place where medical care is given, like a hospital, clinic, or lab. This policy informs them about when a service may be covered.
**Note:** Initial approval period for drugs listed below will be 3 months. Continued approval beyond the first 3 months will require documentation showing objective response to therapy.

Evidence Review

Description

Prostate cancer is a neoplastic disease of the prostate gland. Prostate cancer arises from mutations in cells of the prostate that cause overexpression of enzymes that support androgen biosynthesis, loss of regulation of cell death within the tumor cells, and up regulation of androgen receptors. Androgen receptor binding by androgens plays a crucial role in prostate cancer progression. Most prostate cancers respond to androgen deprivation.

Approximately 60% of all cases of prostate cancer are diagnosed in men 65 years of age or older and 97% occur in men 50 and older. CRPC is a term used to describe prostate cancer which has progressed despite local therapy and first-line hormonal therapy assuring castrate levels of testosterone. Prostate cancers typically progress slowly and there is a high rate of survival for disease detected in early stages, but not for advanced disease stages. In the US, the 5-year survival rate is effectively 100% when the disease is local or regional, but this drops to 31% for disease with distant metastases.

Disease Burden

Prostate cancer is the second most common cause of cancer death in American men. In 2013, an estimated 238,590 men are expected to be diagnosed with prostate cancer, and approximately 29,720 are expected to have died from the disease. While it is prevalent, only 15% of all prostate cancer patients develop mCRPC prior to chemotherapy, and just 9% of all prostate cancer patients progress to mCRPC on first-line docetaxel chemotherapy.

The condition is associated with a substantial economic burden, due to high incidence rates and high costs associated with management of advanced cancer stages. The high management cost burden arises from the requirement for hospitalizations, chemotherapy, palliative surgical procedures, and computed tomography (CT) or magnetic resonance imaging (MRI) scans to monitor potential bone metastases. In 2007, per-patient per-month CRPC costs for men over the...
age of 40 were approximately $1,800, with ambulatory visits ($1,152) and inpatient stays ($559) comprising the majority of these costs. Total all-cause healthcare costs for these same patients totaled $3,500 per-patient per-month.

### Rationale

**Treatment Alternatives**

Several approved pharmacotherapeutic alternatives for mCRPC have demonstrated some benefit in estimated survival compared with acceptable controls.

**Zytiga® (abiraterone) + prednisone**

Zytiga® (abiraterone) acetate is an oral drug that is converted in vivo to abiraterone a CYP17 complex (17α-hydroxylase/C17,20-lyase) inhibitor that interrupts androgen biosynthesis throughout the body (testes, adrenal gland, and prostate tumor). Prostate cancer is very often an androgen-driven disease. CYP17 inhibition may also lead to increased mineralocorticoid production by the adrenal gland secondary to increased adrenocorticotropic hormone (ACTH) production from a feedback mechanism induced by low cortisol levels. Up regulated ACTH leads to increased deoxycorticosterone which exhibits mineralocorticoid activity. Results from clinical trials have shown that coadministration of a corticosteroid (eg, prednisone) with abiraterone reduces the incidence and severity of mineralocorticoid excess associated adverse reactions. An RCT showed that abiraterone and prednisone improved radiographic progression-free survival, time to initiation of chemotherapy, time to onset or worsening of pain, and time to deterioration in improvement status.

**Xtandi® (enzalutamide)**

Xtandi® (enzalutamide) is indicated for the treatment of mCRPC in patients who have received prior chemotherapy containing docetaxel. One well-designed RCT has shown enzalutamide prolongs overall survival (OS) by 4.8 months, time to prostate-specific antigen (PSA) progression (TTPP), radiographic progression-free survival (rPFS), and time to first skeletal-related event (SRE) compared with placebo. There is currently no direct evidence with which to assess real world comparative effectiveness. Indirect evidence suggests a similar modest (2-5 month) increase in overall survival and hazard for risk of death with enzalutamide, abiraterone, or
cabazitaxel in patients with mCRPC previously treated with a docetaxel-based regimen. However, it is important to note that the abiraterone and cabazitaxel studies had control arms which included agents with anti-tumor activity (prednisone and mitoxantrone + prednisone, respectively) compared to placebo control for enzalutamide. Evidence of safety is currently limited. The most significant toxicity reported for Xtandi® (enzalutamide) is seizure, although this occurs rarely (incidence about 1%).

Indirect evidence suggests favorable safety and tolerability compared to other second-line treatments with survival benefit for mCRPC. Enzalutamide lacks the detrimental effects of mineralocorticoid excess induced by Xtandi® (enzalutamide), and thus does not require co-administration with corticosteroids, which may complicate CRPC treatment. Unlike Jevtana® (cabazitaxel), Xtandi® (enzalutamide) is not reported to commonly cause neuropathy or severe myelosuppression, two significant toxicities which can lead to morbidity and limit additional therapy in this patient population.

**Guideline Recommendations**

The latest prostate cancer guidelines from the NCCN recommend the following systemic therapies for advanced disease (primarily category 2a unless otherwise labeled):

**Metastatic castration-recurrent prostate cancer**

**Asymptomatic visceral disease:** Sipuleucel-T or secondary hormone therapy (including abiraterone or enzalutamide) or docetaxel or clinical trial

**Bone metastases:** Denosumab(1) or zoledronic acid(1)

**Disease recurrence post-abiraterone or enzalutamide or intolerance:** Docetaxel (1) or abiraterone or enzalutamide or Radium-223 for symptomatic bone metastases (1) or Sipuleucel-T* or other secondary hormone therapy or clinical trial.

**Disease recurrence post-docetaxel or first-line therapy intolerance:** Abiraterone (1, post-docetaxel) or enzalutamide (1, post-docetaxel) or cabazitaxel (1, post-docetaxel) or salvage chemotherapy or docetaxel rechallenge or mitoxantrone or other secondary hormone therapy or Provenge® (sipuleucel-T) * or clinical trial

*Note: Provenge® (sipuleucel-T) is recommended only for asymptomatic or minimally symptomatic patients with an ECOG performance status of 0-1. It is not indicated for patients with hepatic metastases or life expectancy <6 months.

**General:** Maintain castrate serum testosterone levels
**Symptomatic visceral disease:** Docetaxel or mitoxantrone (for patients not candidates for docetaxel) or abiraterone or enzalutamide or palliative care for symptomatic bone metastases or clinical trial

These guidelines are generally aligned with evidence-based European guidelines, excepting the adoption of use of Xtandi® (enzalutamide).

**Non-Metastatic castration-resistant prostate cancer**

NCCN guidelines recommend apalutamide, especially if PSA doubling time is < 10 months. Additionally, bone support should be used in patients receiving this medication (fracture 11% vs 6.5% placebo).

**National Comprehensive Cancer Network (NCCN) Compendium**

The National Comprehensive Cancer Network (NCCN) Drugs and Biologics Compendium is based directly on the NCCN Clinical Practice Guidelines in Oncology. The compendium lists specific panel recommendations for off-label uses of drugs, and each recommendation is supported by a level of evidence category.

The NCCN Categories of Evidence and Consensus used in the recommendations are:

- **Category 1:** The recommendation is based on high level evidence (eg, randomized controlled trials) and there is uniform NCCN consensus.

- **Category 2A:** The recommendation is based on lower level evidence and there is uniform NCCN consensus.

- **Category 2B:** The recommendation is based on lower level evidence and there is nonuniform NCCN consensus (but no major disagreement).

- **Category 3:** The recommendation is based on any level of evidence but reflects major disagreement.
2014 Update

A search of the literature from 7/1/13 to 10/31/14 did not identify new evidence requiring changes to this policy.

2015 Update

Updated new indications and NCCN recommendations for Xtandi® (enzalutamide). A search of the literature from 7/1/14 to 8/31/15 did not identify new evidence requiring changes to this policy.

2016 Update

Updated policy based on new NCCN recommendations. Zytiga® (abiraterone acetate) step removed for Xtandi® (enzalutamide).

2018 Update

Updated new product labeling and NCCN recommendations which now include Erleada™. A search of the literature from 4/11/2017 to 3/13/2018 did not identify new evidence requiring changes to this policy. Yonsa® (abiraterone) criteria was added.
